Abstract

Gender violence is a problem that has been increasing in recent years as a consequence of intolerance and cultural diversity in personal and social relationships. The aim of this study was to describe the scientific evidence on gender violence between intimate partners. The methodology used was the narrative review and analysis of articles published between 2019 and 2022 in the Scopus, EBSCO and Jane’s databases, obtaining a total of 21 articles. The findings show that the existence of gender violence is a social problem that causes frustrations transferred to the partner, most of whom are women who report the various types of violence: physical, economic, sexual, emotional and psychological abuse. The main characteristics of violence are related to male dominance in the relationship, social isolation and subjugation of power due to economic, educational and cultural deficiencies, among others. It is concluded that exposure to violence requires timely psychological interventions that can mitigate the impact on mental health, which is why a comprehensive policy response is needed to benefit vulnerable populations.

Keywords: gender violence, types of violence, characteristics

1. Introduction

Nowadays, violence is a global health problem because it is a clear violation of human rights. The World Health Organization (WHO) indicates that one out of three women in the world has suffered some form of violence. Likewise, according to statistical reports, almost one third (27%) of women between 15 and 49 years old are exposed to physical harm. The prevalence of physical abuse of women is around 20% in Western Pacific countries, 22% in Europe, 25% in the Americas, 33% in
African regions, 31% in the Eastern Mediterranean and 33% in Southeast Asian countries. These figures have been increasing, since violence has social, economic, cultural and other costs for society (World Health Organization, 2021), (García-Moreno, 2013).

Within this context, there are several factors associated with violence, including: low educational level, domestic violence, stress in the aggressor, mental health problems, excessive consumption of psychotropic substances, economic problems and macho behavior, where the male assumes a dominant position over the partner, exhibiting this gender inequality (López-Hernández & Rubio-Amores, 2020). Considering the above, it is evident that different forms of intimate partner violence can cause femicide, stress, and increase the occurrence of psychological disorders that affect mental health (Vargas, 2017).

In this sense, gender violence is exercised to a greater extent by former intimate partners and is presented in different categories: psychological, physical, sexual, economic and patrimonial. The consequences of gender violence at the legal level still present evident gaps, which is called normative blindness, specifying the scarcity of an updated normative framework for the interpretation and analysis of acts involving gender violence in society (Ferrer-Pérez & Bosch-Fiol, 2019).

Due to the presence of COVID-19 globally, contagion forced confinement within the home, causing increased exposure to abusive behaviors and risk factors for violence against women by their partners (Mateos Casado, 2021). On the other hand, crises, catastrophes and times of upheaval are aggravating factors in the mistreatment and abuse of female intimate partners, and it is undeniable that these situations have a social, cultural and economic cost in the family environment, especially for couples. As a consequence, the woman feels vulnerable, incapacitated and isolated to act against her aggressor, which reduces her motivation to look for immediate help (Ruiz-Pérez & Pastor-Moreno, 2021).

Finally, this problem is latent and brings with it serious consequences in various human spheres, including health (increased morbidity and mortality), economic, social and legal aspects, among others. Therefore, it is necessary to analyze gender violence to learn about this phenomenon (Rivas-Rivero & Bonilla-Algovia, 2022), (Thulin et al., 2022), in order to propose strategies for psychological interventions early and prevent mental health problems in the future (Adejumo et al., 2022), (Wight et al., 2022), not only of the woman but also of the family.

2. Methodology

The study is a narrative review (Moreno et al., 2018); three specialized databases were searched: Scopus, EBSCO and Jane’s, in which full-access texts corresponding to the years 2019 to 2022 were collected, since the pandemic has been present in that period of time. Only scientific articles were selected, opting for the term gender-based and using the Booleans “and”, “or”, adding the term intimate partner violence or domestic violence to exclude some other studies. Finally, an exhaustive review of the topic and content of each article was carried out, leaving 21 suitable for the study, and research from different countries was considered, working only with English and Spanish. Within the databases, articles were also excluded for duplicity and others for not having any link with the topic to be investigated.

## 4. Discussion

The findings in the review of scientific articles make the problem of gender-based violence visible. It is nowadays a new global social and economic pandemic (Averis, 2021), (Velzeboer et al., 2021), which has increased dramatically during the presence of COVID-19, as shown by morbidity and mortality statistics (López-Hernández & Rubio-Amores, 2020). In this sense, COVID-19 has highlighted the fragility of health systems worldwide in the face of the other pandemic of violence (Chandan, 2020).

### 4.1 Types of violence in intimate partners

It is important to highlight that social isolation forced women to spend more time with the aggressor, increasing tensions and abuse at home permanently (Hsu & Henke, 2021), (Ferrer-Pérez & Bosch-Fiol, 2019). These events of domination and fear provoked by gender violence are a huge obstacle for women to report abuse or violence perpetuated by their partners, this being a potential risk factor for cases of feminicide (Espinoza Carvajal, 2020). Fear caused most women to be disconnected from support networks to report attacks by their partners, which put their safety and well-being at risk (Bouillon-Minois et al., 2020), (Ruiz-Pérez & Pastor-Moreno, 2021).

The presence of COVID-19 turned homes into unsafe places for women and children (Leburu-Masigo & Phuti Kgadima, 2020), as all types of violence are generated here, for example, physical, sexual, psychological, interpersonal and emotional abuse (Ruiz-Pérez & Pastor-Moreno, 2021), and even intimidation, coercion, trauma and deprivation of freedom occur, especially among women in precarious economic and working conditions (Bellizzi et al., 2020), generating a negative impact on their mental and psychological health and their domestic environment (Raj et al., 2020), (Buttell & Ferreira, 2020).

Regarding the types of violence, economic and patrimonial violence have been highlighted due to excessive domestic work without any type of retribution; symbolic and institutional violence has been represented in governmental and institutional responses; in intrafamilial or domestic violence, the unfair power dynamics have been highlighted, which has allowed a lower aptitude in women to face violence, putting their children and themselves at risk (Londoño Bernal, 2020). On the other hand, the culture of violence has been related to lack of gender identity, inappropriate sexual behavior, lack of communication skills and values (Rollston et al., 2020).

### 4.2 Characteristics of Violence in the family environment

In the family environment, women are responsible for the care of their children, and when they are victims or survivors of violence, they become vulnerable and fragile in the social environment, with
low self-esteem (Chaparro Moreno & Alfonso, 2020). This problem has emerged in both rural and urban areas (Moffitt et al., 2020), as well as in immigrant women (Sabri et al., 2021), (Ruiz-Pérez & Pastor-Moreno, 2021).

The violence added to the effects of the pandemic, such as unemployment and poverty, generated economic stress and financial uncertainty in the poorest households. International studies indicate that the characteristics of violence during the quarantine period were physical and sexual abuse, rape and intimidation of the woman by the aggressor for not being reported. However, economic, social, patrimonial, verbal, symbolic and institutional violence have also been considered relevant (Gebrewahd et al., 2020).

Likewise, submission to power has increased the possibility of traumatic experiences that lead to situations of illness due to blows, punches, shoves, kicks, burns, threats with sharp weapons that can even lead to feminicide (Manrique De Lara & Medina Arellano, 2020). Conflicts are related to arguments due to lack of economic resources to meet basic household needs. Likewise, this situation has notably damaged mental health through anxiety, depression, post-traumatic stress, feelings of loneliness, sadness, low self-esteem, anger, exhaustion, suicidal ideation due to the restriction imposed on the partner to maintain social contact, weakening support networks (Jiménez-Rodríguez et al., 2020).

In this sense, in order to provide viable solutions against any act or type of aggression against women, it is evident the need to work and implement actions, strategies and policies of cultural evolution for the benefit of reducing violence against them (Donato, 2020), or changing the patriarchal society and gender inequality (Silveira Campos et al., 2020), (Roesch et al., 2020). Given the above, violence is a public health problem that has evolved over time and has a negative impact on the mental, physical and sexual health of women, causing an internal and/or external imbalance that leads to a deterioration in the quality of life and personal development in the family environment (Beyene et al., 2022).

Gender roles in relationships within couples may have opposing ideas or ways of thinking due to behaviors, cultural patterns, customs, among others, causing these differences in some form of physical and sexual violence (Rodney et al., 2022), (Rivas-Rivero & Bonilla-Algovia, 2022), (Gamarel et al., 2022). In addition, violence occurs in various scenarios where social relationships are promoted (Taha-Thomure et al., 2022) and is prevalent in immigrant and impoverished women (Scheer et al., 2022), (Sabri et al., 2021).

Finally, gender violence is a serious problem faced by most women, which unfortunately is inherited from generation to generation and seriously affects their personal and integral development, due to the close presence of the aggressor and the dominance he exercises over their actions. There is also evidence of economic deprivation, negative feelings and emotions of frustration that are transferred to the partner through physical, economic, sexual, emotional and psychological abuse.

According to scientific evidence, the most prevalent types of violence are: physical, psychological and sexual, since these are the cases, most reported by women. Likewise, the characteristics of gender violence in the family environment are mostly related to the aggressor’s dominance in the relationship, social isolation and subjugation of power due to economic, educational and cultural deficiencies, among others, which have widely increased as a consequence of the pandemic and its aftermath. This is confirmed by information gathered by various professionals and research. It is suggested that more research be conducted on the phenomenon of gender violence in order to expand knowledge for timely psychological interventions for the benefit of society.

5. Conclusions

It is concluded that intimate partner violence is a multidimensional phenomenon that involves power and control dynamics based on the concept of gender and its roles, with constant patterns of increasing tension, states of violence and reconciliation. It is a situation that has serious
consequences for the health and well-being of the victims, who often face obstacles in seeking help. In this regard, it is necessary to consider a comprehensive approach from the prevention of the victim, in order to provide an immediate response to this social problem, to promote gender equality at all levels, a culture of respect in the couple and in society, and to ensure that victims have access to support services and justice.
